

SPECIFICATION

TO ALL WHOM IT MAY CONCERN:

BE IT KNOWN THAT WE, AKIO ISHIDA, a citizen of Japan residing at Kanagawa, Japan and HISASHI ISHIMURA, a citizen of Japan residing at Kanagawa, Japan have invented certain new and useful improvements in

PRINTER CONFIGURATION DATA SETTING METHOD AND
SERVER USING THE PRINTER CONFIGURATION DATA

of which the following is a specification:-

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to technology for reflecting configuration data of a printer on a printer driver in a server used for server-based environment (for example, "Metaframe" environment) in which applications run only in the server.

2. Description of the Related Art

To solve problems of a conventional client/server system, there is a system in which application programs run only in a server instead of in clients. A system introducing the Metaframe server is an example of such a system.

Fig.1 shows an example of the Metaframe environment. An application program run on an Metaframe server 1, and a client 2 only displays execution results of the application program.

To use a printer 3 in the Metaframe environment, for example, a printer driver is installed in the Metaframe server 1 beforehand, and a logical printer of the printer 3 is auto-created when the client 2 that uses the printer 3 logs to the Metaframe server 1. When printing is performed from the client 2, print data is generated in the Metaframe server 1, and the print data is redirected to the printer 3 via the

client 2, so that the printer 3 prints the print data.
According to the printer auto-creation in the Metaframe
environment, although the application is running only
in the server, the user can print from the application
5 running on the Metaframe server 1 to her local printers,
just like she can print from local applications. For
example, "Inside Citrix Metaframe XP" of Addison-Wesley
refers to the printer auto-creation process in more
detail.

10 In addition, US2002/0018234A1 discloses a
conventional technology of a Metaframe print system.
The US2002/0010234A1 discloses a universal printer
driver that can be used in the Metaframe environment.

In the printer system of the Metaframe
15 environment, there is a problem in that, although
printer options are set in the client side printer
driver, the option setting is not reflected on the
printer driver in the Metaframe server side in the
printer auto-creation process.

20 That is, option setting in the logical
printer remains default setting. For example, even if
the printer has a double-sided tray, the setting of the
auto-created logical printer remains no double-sided
tray. In addition, settings for paper size and paper
25 type of tray remain default.

SUMMARY OF THE INVENTION

An object of the present invention is to provide technology to reflect configuration data of a printer on a printer driver on the server in an environment in which application programs run only on the server instead of on clients.

The above object is achieved by a method for setting configuration data of a printer for a printer driver in a server of an image printing system that includes a client, the printer and the server including the printer driver for the printer, the method including the step of:

storing the configuration data obtained from the printer into the server;

wherein a configuration data obtaining part in the server reads the stored configuration data according to a request from the printer driver, and sends the configuration data to the printer driver.

According to the present invention, since the configuration data is stored in the server and the configuration data obtaining part provides the configuration data to the printer driver, the configuration data can be reflected on the printer driver. Therefore, the user can print something by

performing option setting such as tray setting and the like even in, for example, a Metaframe environment in which the server cannot obtain the configuration data from the printer.

5

BRIEF DESCRIPTION OF THE DRAWINGS

Other objects, features and advantages of the present invention will become more apparent from the following detailed description when read in conjunction
10 with the accompanying drawings, in which:

20 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

As described in the related art, there is a problem in that option setting in the printer driver in the client side is not inherited to the printer driver in the Metaframe server. The reason of the problem will be described in the following.

In a normal configuration including the client 2 and the printer 3 shown in Fig.2, the client 2 and the printer 3 performs bidirectional communication so that option data such as the double-sided Lay of the printer 3 can be obtained by the client 2. The bidirectional communication is performed, for example, in a configuration shown in Fig.3. In this configuration, a network communication module 6 obtains information specified by a bidirectional communication module 5 from the printer 3 via a network by using a protocol such as SNMP, in which the bidirectional communication module 5 is a part of the printer driver 4.

However, the above-mentioned bidirectional communication is not available between the Metaframe server 1 and the printer 3 in the Metaframe environment. Therefore, the option data can not be obtained by the printer driver in the Metaframe server. Thus, the above-mentioned problem arises.

In the following, embodiments of the present invention will be described.

(Outline of system configuration)

In the present embodiment, in an network environment shown in Fig.1, the client 2 obtains configuration data (option setting data) of the printer

3 by using a configuration data obtaining tool, in
which the configuration data can not be obtained from
the Metaframe server by the bidirectional communication.
The configuration data is stored in the Metaframe
5 server 1 (hereinafter, the configuration data will be
also called as pseudo-bidirectional communication data).

The Metaframe server 1 accesses the stored
data so that the printer driver in the Metaframe server
1 obtains the configuration data, and the configuration
10 data can be reflected on the option setting of the
auto-created logical printer.

Fig.4 shows a software module configuration
in the Metaframe server 1 (enclosed by a solid line
square). For comparison, a conventional configuration
15 is shown enclosed by a dotted line square.

As shown in Fig.4, the network communication
module 6 is not used, but, a pseudo network
communication module 7 is used. Accordingly, the
printer driver 4 obtains configuration data, via the
20 pseudo network communication module 7, from the pseudo
bidirectional communication data 8 that is stored
beforehand.

(Flow of processing)

Next, processing in the present embodiment
25 will be described in more detail with reference to

Figs.5-7.

Fig.5A is a figure for explaining how to obtain configuration data by the client 2. As shown in the figure, the client 2 in which the configuration data obtaining tool runs obtains the configuration data.

At this time, for example, the client 2 displays a window shown in Fig.6 so that the user of the client 2 selects a printer driver installed in the client 2. As a result, a printer from which configuration data is to be obtained is specified. Then, the client obtains data from the specified printer and stores the obtained data. The mechanism for obtaining the configuration data by using the configuration data obtaining tool is the same as the mechanism in which configuration data is obtained by a printer driver (bidirectional communication module) and the network communication module as shown in Fig.3.

The configuration data obtaining tool can be also installed in a server instead of in a PC as long as a printer driver for the target printer is installed in the server or the PC.

Next, as shown in Fig.5B, the configuration data 8 and the pseudo network communication module 7 are installed in the Metaframe server 1 by copying the configuration data 8 and the pseudo network

communication module 7 in a predetermined folder in the Metaframe server 1. The pseudo network communication module 7 may be installed beforehand.

It is also possible to store the configuration data 8 in the client 2 so that the Metaframe server 1 obtains the data via a network. However, since it is desirable to decrease data amount transmitted over the network in the Metaframe environment, the configuration data is stored in the server 1 according to the present embodiment.

Next, procedure for reflecting configuration data on the printer driver in the server will be described with reference to Fig.7. The following processing can be performed when the logical printer is auto-created, or when the user of the client opens a property screen of the printer driver after the logical printer is created.

In Fig.7, first, the printer driver outputs an option data obtaining request to the bidirectional communication module 5 in step 1. The option data obtaining request includes an instruction indicating which items of configuration data to obtain such as tray information and the like. Next, the bidirectional communication module 5 checks whether the pseudo network communication module 7 exists in step 2.

If the pseudo network communication module 7 does not exist (NO in step 3), the server notifies the bidirectional communication module 5 that the process fails in step 4, and the process ends. If the pseudo network communication module 7 exists (Yes in step 3), the pseudo network communication module 7 is called and the pseudo network communication module 7 obtains configuration data corresponding to the option data obtaining request from the configuration data file 8 in step 5. After that, the read data is output to the bidirectional communication module 5 in step 6. The obtained configuration data is reflected on setting of the printer driver in step 7.

(Details of the pseudo network communication module)

Next, the configuration of the pseudo network communication module will be described in detail, in which the pseudo network communication module is compared with the normal network communication module.

Fig.8A shows the configuration of the conventional network communication module 6. Fig.8B shows the configuration of the pseudo network communication module 7 of the present embodiment.

As shown in Fig.8A, the conventional network communication module 6 includes API (application program interface) 61, a converting part 62, a MIB

obtaining/analyzing part 63, and a protocol implemented
part 64. The API 61 is for interfacing between the
application program for specifying information to be
obtained and the network communication module 6. The
5 API is a set of functions, for example, each of which
corresponds to a piece of MIB data. The function
itself may be called as an API. The converting part
62 converts between information specified by the
application via API and MIB data. The MIB
10 obtaining/analyzing part 63 obtains and analyzes MIB
data on the printer. According to this configuration,
the network communication module 6 can obtain
configuration data (option data) that is MIB data by
using bidirectional communication.

15 As shown in Fig.8B, the pseudo network
communication module 7 includes API 71 that is the same
as that of the conventional network communication
module 6. In addition, the pseudo network
communication module 7 includes a file search/ data
20 obtaining part 72 and a file accessing part 73. The
file search/data obtaining part 72 determines which
piece of configuration data to obtain in the
configuration data file according to information
specified by the API 71 and searches the file and
25 obtains the piece of configuration data. The file

accessing part 73 performs processing for actually
accessing the file.

In the configuration shown in Fig.8B, the API
71 and the API 61 are the same. Thus, from the
5 viewpoint of the bidirectional communication module,
the pseudo network communication module 7 and the
network communication module 6 appear to be the same.
Therefore, a printer driver same as a conventional
printer driver can be used in the Metaframe server
10 according to the present invention.

The pseudo network communication module can
be stored in a recording medium such as an IC card, CD-
ROM and the like, so that the pseudo network
communication module can be installed in the server
15 from the recording medium. The pseudo network
communication module can be also installed in the
server via a network.

(Relationship between the pseudo network
communication module and the configuration data
20 obtaining method)

Next, the relationship between the pseudo
network communication module and the configuration data
obtaining method will be described with reference to
Fig.9.

25 As mentioned before, the configuration data

is obtained by the client 2 by using a software configuration similar to that for performing conventional bidirectional communication. That is, as shown in client side configuration in Fig 9, the
5 configuration data obtaining tool obtains configuration data by using SNMP via APIs in the network communication module 6. Since the configuration data is obtained by using the conventional APIs, the configuration data can be obtained API by API. Thus,
10 data file in which configuration data includes API by API is stored in the Metaframe server as the configuration data file.

For obtaining the configuration data in the client, the configuration obtaining tool calls all APIs
15 in step 11, and obtains configuration data (parameters) corresponding to the APIs and stores the configuration data as the configuration data file in step 12, in which each piece of the configuration data is associated with a corresponding API.

20 By storing the configuration data in such a format, the pseudo network communication module 7 in the server can use APIs same as the APIs that are conventionally used in a printer driver in the client. Thus, the pseudo network communication module 7 can
25 read, from the configuration data file, pieces of

configuration data requested by the bidirectional communication module in the printer driver in the Metaframe server, and can return the pieces of configuration data to the bidirectional communication module in step 13. The pseudo network communication module 7 can read the pieces of configuration data without changing the configuration data.

(Embodiment in which a plurality of printer drivers are used for a printer)

10 It is possible to use a plurality of printer drivers for a printer in this embodiment. This embodiment will be described with reference to Fig.10.

 In this embodiment, there is a case in which each printer driver needs different configuration data.
15 That is, the printer driver 1 obtains data A and the printer driver 2 obtains data B.

 In such a case, the configuration data obtaining tool calls all APIs (including APIs corresponding to A and B) in step 21, and stores pieces
20 of configuration data (including A and B) corresponding to the APIs obtained from the printer's MIB data in step 22, in which each piece of the stored configuration data is associated with a corresponding API. By storing the configuration data in such a form,
25 the pseudo network communication module 7 can read

pieces of configuration data corresponding to APIs that
are requested by the bidirectional communication
modules by using the APIs, and can return pieces of
configuration data to each bidirectional communication
5 module in step 23. Accordingly, the pseudo
communication module 7 can provide configuration data
to a plurality of printer drivers.

According to the present invention, since the
configuration data is stored in the server and the
10 configuration data obtaining part provides the
configuration data to the printer driver, the
configuration data can be reflected on the printer
driver. Therefore, the user can perform option setting
such as tray setting, double-sided unit setting and the
15 like for the auto-created logical printer in the
Metaframe environment in which application programs run
only on the server.

In the server of the present invention, the
application program interface between the configuration
20 data obtaining part and the printer driver in the
server is the same as the application program interface
between a network communication module and a client.
printer driver same as the printer driver in the server,
in which the network communication module is used for
25 obtaining configuration data of the printer for the

client printer driver in a client terminal.

Therefore, a conventional printer driver can be used in the Metaframe server and the configuration data can be reflected.

5 The configuration data obtaining part in the server includes:

 the application program interface;

 a part for determining which piece of configuration data to obtain among the stored
10 configuration data on the basis of information from the application program interface; and

 a part for accessing the configuration data and reads the determined piece of configuration data.
By configuring the configuration data obtaining part in
15 this way, configuration data obtaining part can be realized by a simple configuration compared with the conventional network communication module.

 In the server, the configuration data to be stored in the server is obtained from the printer by
20 using a network communication module that performs bidirectional communication with the printer.

 Thus, by using API that is the same as API of the network communication module for the configuration data obtaining part, the configuration data obtaining
25 part can use the stored configuration data without any

change. The configuration data obtaining part corresponds to the pseudo network communication module.

In addition, the configuration data is obtained by a computer that includes a software tool
5 that causes the computer to display a window for selecting at least one printer driver included in the computer and to obtain configuration data from a printer corresponding to the selected printer driver.

In addition, the client, instead of the
10 server, may store the configuration data, and the configuration data obtaining part in the server may obtain the configuration data from the client.

The present invention is not limited to the specifically disclosed embodiments, and variations and
15 modifications may be made without departing from the scope of the present invention.
